

Iron making in Alabama Volume 4

This historic book may have numerous typos and missing text. Purchasers can download a free scanned copy of the original book (without typos) from the publisher. Not indexed. Not illustrated. 1896 Excerpt: ...and the non-coking constituents of the coal, is not known. When, however, such coals are pulverized they often make excellent coke. The composition of the ash of coke, by affecting its fusibility, may affect also its strength, the size and shape of the cells and the thickness of the cell walls. But of such matters very little is known. It requires a great deal of time to make such investigations, as well as skill and perseverance. The composition of the ash of coal, whatever effect it may have on the quality of the coke made from it, certainly has an important bearing on furnace practice. It must influence the fusibility of the burden, and to a greater or lesser degree affect the consumption of limestone, whether this be the carbonate of lime in the hard ore, or extra stone. The more acid the ash the more base is required for fluxing. The amount of coke used per ton of iron varies, of course, with the nature of the coke, and of the other constituents of the burden; with the kind of iron made, the shape and size of the furnace, the rate of driving, and other circumstances grouped generally under the term furnace practice. The range is from 1.16 to 1.72 tons of 2240 pounds. From an examination of 150;000 tons of iron made from 1890 to 1895 under varying conditions the lowest consumption for a period of one month was 1.16 tons per ton of iron. In this particular case the furnace was working on all brown ore, the burden being composed of brown ore 52.9, limestone 20.4, and coke 26.7. The tons of,1 iron made per charge was 1.53 tons, number of charges 1802, total iron made 2766 tons, of which 99.1 per cent, was of foundry grades. The consumption of materials per ton of iron made was ore 2.31

tons, stone 0.89 ton, and coke 1.16. For further information...
